## **CSc 352**

# C Programming files

Benjamin Dicken

## The UNIX File System

- The file system is a core component to a UNIX operating system
- There are different specific implementations, but there are shared general-principles
  - UFS, EXT2, EXT3, EXT4, ZFS, etc, etc
- We will focus on the general principles

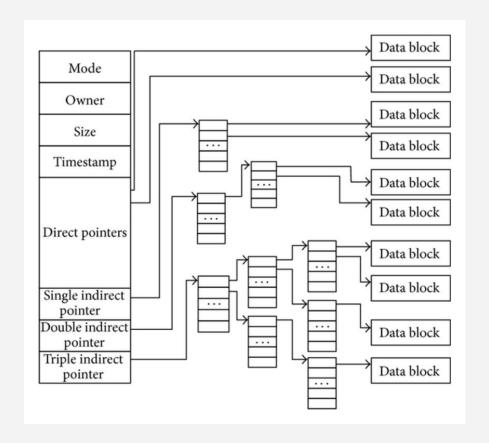

#### Files vs Directories

- A "regular" file (.txt, .c, .out, etc) and a directory are both just files
- A directory files contains a list of inodes including itself, its parent, and its child inodes
- Try: \$ 1s -1

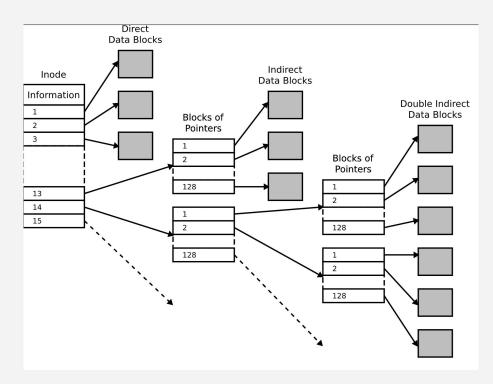

#### **iNodes**

- Behind the scenes, a file is really a node containing a collection of metadata and pointers to blocks of the actual data
- These nodes are called inodes
- The file systems stores a table or a tree of **inodes** on the actual hard drive

## iNodes pointer structure

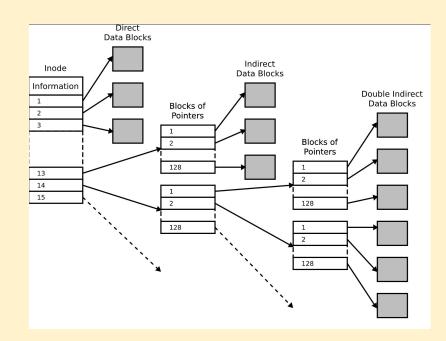

- For small files, can store data within the blocks from the direct pointers
- For larger files, use some of the indirect pointers
- Find block size: \$ stat -f /
- Inode number: \$ 1s -i

#### Activity

## How big will the file be?

How many block pointers will be required for a text file with 100,000 ascii characters with a block size of 4096 bytes and a block pointer size of 64 bits?

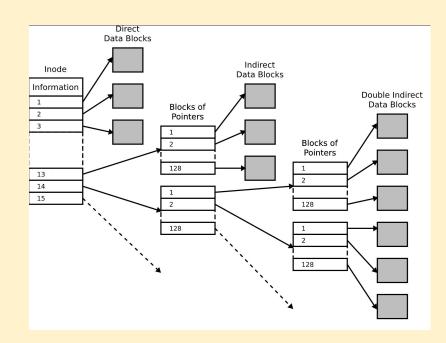

#### **Activity**

## How big will the file be?

How many block pointers will be required for a text file with 100,000 ascii characters with a block size of bytes and a block pointer size of 64 bits?

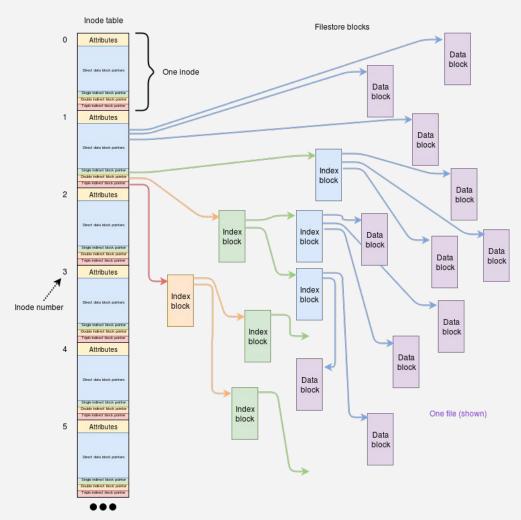

#### 26

(12 in the inode, 1 indirect, 13 in the block of pointers)

#### **iNodes**

- iNodes themselves are stored in a known location on a hard drive
- Can be an array / table
   or B / B+ tree

## File-related Commands

stat

df

ls -i

## Text File I/O in C

- Can read and write text to and from files
- Similar to reading/writing to stdin/stdout
- stdio/stderr are basically just "files" that have already been opened for you

```
#include <stdio.h>
#include <errno.h>
int main() {
  FILE* test file;
  test file = fopen("file.txt", "w");
  if (test_file == NULL) {
    fprintf(stderr, "Opening file failed with code %d.\n", errno);
    return 1;
  fprintf(test file, "Number: %d\n", 25);
  fflush(test file);
  fclose(test file);
  return 0;
```

```
#include <stdio.h>
                             What is a FILE*?
                                                    Many different possible modes
#include <errno.h>
                                                    (see man pages)
int main() {
  FILE* test_file;
  test_file = fopen("file.txt", "w");
  if (test_file == NULL) {
    fprintf(stderr, "Opening file failed with code %d.\n", errno);
    return 1;
                                                      Same function, different
                                                      locations to send the output to
  fprintf(test_file, "Number: %d\n", 25);
  fflush(test file);
  fclose(test file);
                                                         See man pages for fopen,
  return 0;
                                                         fprintf, fflush, fclose, fscanf
```

## Implement Sum

Write a C program that

- 1. Prompts the user for a file name
- 2. Opens this file
- 3. Reads through each line of file, assuming each line will have exactly 1 integer number
- 4. Sum the numbers, save the result to sum.txt

#### What is a FILE?

A structure containing the necessary information to manage that particular file

See the standard!

http://port70.net/~nsz/c/c11/n1570.html

#### What is a FILE?

Investigate on lectura. You can use:

```
$ locate stdio.h
```

```
$ echo '#include <stdio.h>' | cpp -H -o /dev/null 2>&1 | head -n1
```

Can you figure out what a FILE actually is?

## What is a FILE?

/usr/include/stdio.h

/usr/include/x86\_64-linux-gnu/bits/types/struct\_FILE.h

```
#include <stdio.h>
int main() {
  FILE* test file;
  char line[128];
  test file = fopen("data.txt", "r");
  if (test file == NULL) {
    fprintf(stderr, "error opening the file.\n");
                                                           Third parameter for fgets is just
                                                           a FILE*
    return 1;
  while (fgets(line, 127, test file) != NULL) {
      printf(">%s<\n", line);</pre>
  fclose(test file);
  return 0;
```

## Function summary

- fopen For opening files, getting FILE pointers.
   Can open in various modes
- fscanf / fgets For reading from files
- fprintf For writing to a file
- fflush Ensure that any buffered content gets written to the file stream
- fclose Close the file

## Implement toupper.c

Write a C program that

- 1. Prompts the user for two input files names
- 2. The program should read in the lines from the first, convert alphabetical character to CAPS, and write to the second file
- 3. Close files when done

Each file can have designated permissions for owner, group, and everyone

For each of those, can specify if allowed to **read** and/or **write** and/or **execute** 

ls -1 test.c or stat test.c

Owner can read, write, exec Group can read and exec

Everyone can exec

```
lectura:> stat test.c
 File: test.c
 Size: 175
                    Blocks: 14
                                      IO Block: 131072 regular file
Device: 43h/67d Inode: 4570337 Links: 1
Access: (0751/-rwxr-x--x) Uid: (14358/bddicken) Gid: ( 0/
                                                              root)
Access: 2022-02 21 12:37:09.281929146 -0700
Modify: 2022-02-21 12:37:09.283156247 -0700
Change: 2022-02-21 12:55:26.879605124 -0700
```

#### Chmod

Use chmod to specify permissions

\$ chmod 751 test.c

Sets permissions for test.c to 111101001 or rwxr-x--x

## Chmod

Write the chmod command to set the permissions of the file **test.txt** to be:

r-x--xrwx
